# 1 What is Software?

There are differing definitions of the word *software*, but in general **it is more than just the code**. It is understood to also include the documentation and configuration.

## 1.1 Types of Software

One can differentiate between two general groups of software.

- Generic products.

This includes anything that you would call *shrink-wrapped software*. Examples are Microsoft Office, Open Office, Photoshop, etc.

- Customised products.

These are products that are customised for a particular purpose. Examples of this would be TUCaN (*TU Campus Network*), an air traffic control system, etc.

## 1.2 Properties of Software

Software has some unique properties compared to hardware. For one thing, software does not physically exist, so it's basically free to reproduce. It also doesn't wear out or need to be replaced. It does, however, need to be *maintained*, meaning that it needs to be updated to cope with changing environments, otherwise it will become obsolete. As such, software is also incredibly hard to measure. How could one define (and quantify?) the quality of software? Are certain properties (amount of lines of code, amount of comments) correlated to the quality? How can progress be measured?

# 2 What is Software Engineering?

The term comes from the sixties and is often attributed to F.L. Bauer. It describes the discipline of systematically developing software following engineering principles. This is opposed to an artistic way of software development.

## 2.1 Areas of Software Design

- Software Requirements

*The requirements define what the systems is expected to do.*

- Software Design

*How the system is designed.*

- Software Testing  
*The systematic identification (and elimination) of errors.*
- Software Maintenance
- Software Configuration Management  
*The management of different versions and configuration of a software.*
- Software Engineering Process  
*Definition and improvement of software development processes.*
- Software Engineering Tools and Methods
- Software Quality

## 2.2 Why do Software Projects Fail?

Software development can fail for a large number of reasons.

- The requirements and system dependencies are not well-defined
- Changing the requirements during the development is much, much easier for software than for hardware; □ (Software has to accommodate for hardware “issues”.)
- Lack of tools, methods, education, planning, ...

### Note

A recent paper published was really insightful into the unknowns of software design. The authors specified a system they wanted built, and asked a large number of companies to develop it for them. Afterwards, they compared the budget the companies used for the development, and the timing.

## 2.3 Takeaway

Engineering software is hard; this lecture teaches you why and (to some extent) how to tackle common problems. **Software engineering is about designing software and not about building software.**
